AA203 Optimal and Learning-based Control

iLQR, stochastic optimal control, LQG

Roadmap

LQR extensions

- Linear tracking problems
- LQR with cross-quadratic cost and affine dynamics
- Non-linear tracking problems
- Using LQR to solve non-linear optimal control problems
 - Iterative LQR
 - Differential dynamic programming

Linear tracking problems

• Imagine you are given a *nominal trajectory*

$$(\overline{\boldsymbol{x}}_0, ..., \overline{\boldsymbol{x}}_N), (\overline{\boldsymbol{u}}_0, ..., \overline{\boldsymbol{u}}_{N-1})$$

- Assume nominal trajectory satisfies linear dynamics
- Linear tracking problem: find policy to minimize cost

$$\frac{1}{2}(x_N - \overline{x}_N)' H(x_N - \overline{x}_N) + \frac{1}{2} \sum_{k=0}^{N-1} [(x_k - \overline{x}_k)Q(x_k - \overline{x}_k) + (u_k - \overline{u}_k)R(u_k - \overline{u}_k)]$$

• Then define deviation variables

$$\delta \pmb{x}_k \coloneqq \pmb{x}_k - \overline{\pmb{x}}_k$$
 and $\delta \pmb{u}_k \coloneqq \pmb{u}_k - \overline{\pmb{u}}_k$

and solve standard LQR with respect to deviation variables

LQR with cross-quadratic cost & affine dynamics

Consider the LQR problem with the generalized cost

$$\frac{1}{2}\boldsymbol{x}_k^T Q_k \boldsymbol{x}_k + \frac{1}{2}\boldsymbol{u}_k^T R_k \boldsymbol{u}_k + \boldsymbol{u}_k^T H_k \boldsymbol{x}_k + \boldsymbol{q}_k^T \boldsymbol{x}_k + \boldsymbol{r}_k^T \boldsymbol{u}_k + c_k$$

and dynamics

$$\boldsymbol{x}_{k+1} = A_k \boldsymbol{x}_k + B_k \boldsymbol{u}_k + \boldsymbol{d}_k$$

We can derive an affine optimal feedback law for this system via DP recursion

LQR with cross-quadratic cost & affine dynamics

The cost-to-go at time k takes the form

$$\frac{1}{2}\boldsymbol{x}_k^T P_k \boldsymbol{x}_k + \boldsymbol{p}_k^T \boldsymbol{x}_k + p_k$$

• Optimal control takes the form $oldsymbol{u}_k^* = oldsymbol{l}_k + L_k oldsymbol{x}_k$ with

$$l_k = -(R_k + B_k^T P_{k+1} B_k)^{-1} (\mathbf{r}_k + \mathbf{p}_{k+1}^T B_k + \mathbf{d}_k P_{k+1} B_k)$$
$$L_k = -(R_k + B_k^T P_{k+1} B_k)^{-1} (B_k^T P_{k+1} A_k + H_k)$$

 Equations for the constant/linear/quadratic cost-to-go terms are unwieldy but not hard to derive, and are given in the lecture notes

Nonlinear tracking problems

• Imagine you are given a feasible nominal trajectory

$$(\overline{\boldsymbol{x}}_0, \dots, \overline{\boldsymbol{x}}_N), (\overline{\boldsymbol{u}}_0, \dots, \overline{\boldsymbol{u}}_{N-1})$$

- The tracking cost is still quadratic, but the dynamics are now nonlinear $\overline{x}_{k+1} = f(x_k, u_k)$
- To apply LQR, we can linearize around the nominal trajectory

$$egin{aligned} oldsymbol{x}_{k+1} &pprox f(ar{oldsymbol{x}}_k,ar{oldsymbol{u}}_k) + rac{\partial f}{\partial oldsymbol{x}}(ar{oldsymbol{x}}_k,ar{oldsymbol{u}}_k)(oldsymbol{x}_k-ar{oldsymbol{x}}_k) + rac{\partial f}{\partial oldsymbol{u}}(ar{oldsymbol{x}}_k,ar{oldsymbol{u}}_k)(oldsymbol{u}_k-ar{oldsymbol{u}}_k) \ A & B \end{aligned}$$

• And apply LQR to the deviation variables (with dynamics $\delta \overline{x}_{k+1} = A \delta \overline{x}_k + B \delta \overline{u}_k$)

Non-linear optimal control problem

Consider now non-linear optimal control problem

$$\min_{\mathbf{u}} \sum_{k=0}^{N-1} c(\mathbf{x}_k, \mathbf{u}_k)$$
subject to $\mathbf{x}_{k+1} = f(\mathbf{x}_k, \mathbf{u}_k)$

• Can we apply LQR-techniques to approximately solve it?

Iterative LQR

• Imagine you are given a feasible nominal trajectory

$$(\overline{\boldsymbol{x}}_0, \dots, \overline{\boldsymbol{x}}_N), (\overline{\boldsymbol{u}}_0, \dots, \overline{\boldsymbol{u}}_{N-1})$$

Linearize the dynamics around feasible trajectory

$$m{x}_{k+1}pprox f(ar{m{x}}_k,ar{m{u}}_k) + rac{\partial f}{\partial m{x}}(ar{m{x}}_k,ar{m{u}}_k)(m{x}_k-ar{m{x}}_k) + rac{\partial f}{\partial m{u}}(ar{m{x}}_k,ar{m{u}}_k)(m{u}_k-ar{m{u}}_k)$$

And Taylor expand cost function around feasible trajectory

$$c(\delta \boldsymbol{x}_k, \delta \boldsymbol{u}_k) = c_k + \underbrace{c_{\boldsymbol{x},k}^T}_{\boldsymbol{q}_k} \delta \boldsymbol{x}_k + \underbrace{c_{\boldsymbol{u},k}^T}_{\boldsymbol{r}_k} \delta \boldsymbol{u}_k + \frac{1}{2} \delta \boldsymbol{u}_k^T \underbrace{c_{\boldsymbol{u}\boldsymbol{u},k}^T}_{R_k} \delta \boldsymbol{u}_k + \frac{1}{2} \delta \boldsymbol{x}_k^T \underbrace{c_{\boldsymbol{x}\boldsymbol{x},k}^T}_{Q_k} \delta \boldsymbol{x}_k + \delta \boldsymbol{u}_k^T \underbrace{c_{\boldsymbol{u}\boldsymbol{x},k}^T}_{H_k} \delta \boldsymbol{x}_k$$

Iterative LQR

 By optimizing over deviation variables (using results for LQR with cross-quadratic cost & affine dynamics), we obtain new solution:

$$\{\overline{\boldsymbol{x}}_k + \delta \boldsymbol{x}_k^*\}$$
 and $\{\overline{\boldsymbol{u}}_k + \delta \boldsymbol{u}_k^*\}$

 We can then re-linearize and Taylor expand around this new trajectory, and iterate!

Iterative LQR

- Backward pass (k = N to 0):
 - Compute locally linear dynamics, locally quadratic cost around nominal trajectory
 - Solve local approximation of DP recursion to compute control law
 - Compute cost-to-go
- Forward pass (k = 0 to N):
 - Use control law to update nominal trajectory
- Iterate until convergence

Differential Dynamic Programming (DDP)

- iLQR first approximates dynamics and cost, then performs exact DP recursion
- DDP instead approximates DP recursion directly
 - Define change in cost-to-go J_k under perturbation $(\delta \pmb{x}_k$, $\delta \pmb{u}_k$) as

$$Q(\delta \boldsymbol{x}_k, \delta \boldsymbol{u}_k) := c(\bar{\boldsymbol{x}}_k + \delta \boldsymbol{x}_k, \bar{\boldsymbol{u}}_k + \delta \boldsymbol{u}_k) + J_{k+1}(f(\bar{\boldsymbol{x}}_k + \delta \boldsymbol{x}_k, \bar{\boldsymbol{u}}_k + \delta \boldsymbol{u}_k))$$

• Then, second order expansion

$$Q(\delta oldsymbol{x}_k, \delta oldsymbol{u}_k) pprox rac{1}{2} egin{bmatrix} 1 \ \delta oldsymbol{x}_k \ \delta oldsymbol{u}_k \end{bmatrix}^T egin{bmatrix} Q_k & Q_{oldsymbol{x},k}^T & Q_{oldsymbol{u},k}^T \ Q_{oldsymbol{x},k} & Q_{oldsymbol{x},k} & Q_{oldsymbol{u},k}^T \ Q_{oldsymbol{x},k} & Q_{oldsymbol{u},k} & Q_{oldsymbol{u},k} \end{bmatrix} egin{bmatrix} 1 \ \delta oldsymbol{x}_k \ \delta oldsymbol{u}_k \end{bmatrix}$$

Differential Dynamic Programming (DDP)

The optimal control perturbation is

$$\delta \boldsymbol{u}_k^* = \operatorname{argmin}_{\delta \boldsymbol{u}} Q(\delta \boldsymbol{x}_k, \delta \boldsymbol{u})$$

 Leveraging the approximation, one can re-use LQR results and find that the optimal deviation is

$$\delta oldsymbol{u}_k^* = oldsymbol{l}_k + L_k \delta oldsymbol{x}_k$$

Algorithm proceeds via same forward/backward passes as iLQR

Stochastic optimal control problem (discrete time)

- System: $x_{k+1} = f_k(x_k, u_k, w_k), k = 0, ..., N$
- Control constraints: $u_k \in U(x_k)$
- Probability distribution: $P_k(\cdot | x_k, u_k)$ of w_k
- Policies: $\pi = \{\pi_0 ..., \pi_{N-1}\}$, where $\boldsymbol{u}_k = \pi_k(\boldsymbol{x}_k)$
- Expected Cost:

$$J_{\pi}(\mathbf{x}_0) = E_{\mathbf{w}_k, k=0,...,N-1} \left[g_N(\mathbf{x}_N) + \sum_{k=0}^{N-1} g_k(\mathbf{x}_k, \pi_k(\mathbf{x}_k), \mathbf{w}_k) \right]$$

Stochastic optimal control problem

$$J^*(x_0) = \min_{\pi} J_{\pi}(\boldsymbol{x}_0)$$

Key points

- Discrete-time model
- Markovian model
- Objective: find optimal closed-loop
- Additive cost (central assumption)
- Risk-neutral formulation

Other communities use different notation: Powell, W. B. AI, OR and control theory: A Rosetta Stone for stochastic optimization. Princeton University, 2012.

http://castlelab.princeton.edu/Papers/AIOR_July2012.pdf

Principle of optimality

- Let $\pi^* = \{\pi_0^*, \pi_1^*, ..., \pi_{N-1}^*\}$ be an optimal policy
- Consider tail subproblem

$$E\left[g_N(\boldsymbol{x}_N) + \sum_{k=i}^{N-1} g_k(\boldsymbol{x}_k, \pi_k(\boldsymbol{x}_k), \boldsymbol{w}_k)\right]$$

and the tail policy $\{\pi_i^*, ..., \pi_{N-1}^*\}$

Principle of optimality: The tail policy is optimal for the tail subproblem

The DP algorithm (stochastic case)

Intuition

- DP first solves ALL tail subroblems at the final stage
- At generic step, it solves ALL tail subproblems of a given time length, using solution of tail subproblems of shorter length

The DP algorithm (stochastic case)

The DP algorithm

Start with

$$J_N(\boldsymbol{x}_N) = g_N(\boldsymbol{x}_N)$$

and go backwards using

$$J_k(x_k) = \min_{u_k \in U(x_k)} E_{w_k} \left[g_k(x_k, u_k, w_k) + J_{k+1} \left(f(x_k, u_k, w_k) \right) \right]$$

for
$$k = 0, 1, ..., N - 1$$

• Then $J^*(x_0) = J_0(x_0)$ and optimal policy is constructed by setting $\pi_k^*(x_k) = u_k^*$

Example: Inventory Control Problem (1/3)

- Stock available $x_k \in \mathbb{N}$, inventory $u_k \in \mathbb{N}$, and demand $w_k \in \mathbb{N}$
- Dynamics: $x_{k+1} = \max(0, x_k + u_k w_k)$
- Constraints: $x_k + u_k \le 2$
- Probabilistic structure: $p(w_k=0)=0.1, p(w_k=1)=0.7,$ and $p(w_k=2)=0.2$
- Cost

4/10/19 AA 203 | Lecture 3

Example: Inventory Control Problem (2/3)

Algorithm takes form

$$J_k(x_k) = \min_{0 \le u_k \le 2 - x_k} E_{w_k} [u_k + (x_k + u_k - w_k)^2 + J_{k+1}(\max(0, x_k + u_k - w_k))]$$

for
$$k = 0,1,2$$

For example

$$J_2(0) = \min_{u_2=0,1,2} E_{w_2} [u_2 + (u_2 - w_2)^2] =$$

$$\min_{u_2=0,1,2} E_{w_2} [u_2 + 0.1(u_2)^2 + 0.7(u_2 - 1)^2 + 0.2(u_2 - 2)^2]$$

which yields $J_2(0) = 1.3$, and $\pi_2^*(0) = 1$

Example: Inventory Control Problem (3/3)

Final solution:

- $\bullet J_0(0) = 3.7,$
- $J_0(1) = 2.7$, and
- $\bullet J_0(2) = 2.818$

Problems with imperfect state information

• Now the controller, instead of having perfect knowledge of the state, has access to observations \mathbf{z}_k of the form

$$z_0 = h_0(x_0, v_0),$$
 $z_k = h_k(x_k, u_k, v_k),$ $k = 1, 2, ..., N-1$

 The random observation disturbance is characterized by a given probability distribution

$$P_{v_k}(\cdot | x_k, ..., x_0, u_{k-1}, ..., u_0, w_{k-1}, ..., w_0, v_{k-1}, ..., v_0)$$

• The initial state x_0 is also random and characterized by given P_{x_0}

Control policies

Define the information vector as

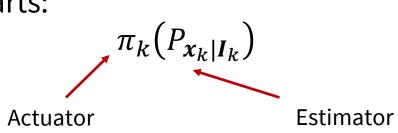

$$I_k = (z_0, ..., z_k, u_0, ..., u_{k-1}), I_0 = z_0$$

- Focus is now on admissible policies $\pi_k(I_k) \in U_k$

• We want then to find an admissible policy that minimizes
$$J_{\pi} = E_{\substack{x_0, w_k, v_k \\ k=0, \dots, N-1}} \left[g_N(\mathbf{x}_N) + \sum_{k=0}^{N-1} g_k(\mathbf{x}_k, \pi_k(\mathbf{I}_k), \mathbf{w}_k) \right]$$

Solution strategies

- 1. Reformulation as a perfect state information problem (main idea: make the information vector the state of the system)
 - Main drawback: state has expanding dimension!
- 2. Reason in terms of sufficient statistics, i.e., quantities that ideally are smaller than I_k and yet summarize all its essential content
 - Main example: conditional probability distribution $P_{m{x}_k|m{I}_k}$
 - Condition probability distribution leads to a decomposition of the optimal controller in two parts:

LQG

Discrete LQG: find admissible control policy that minimizes

$$E\left[x_N'Qx_N+\sum_{k=0}^{N-1}(x_k'Q_kx_k+u_k'R_ku_k)\right]$$

subject to

- the dynamics $\boldsymbol{x}_{k+1} = A_k \boldsymbol{x}_k + B_k \boldsymbol{u}_k + \boldsymbol{w}_k$
- the measurement equation $z_k = C_k x_k + v_k$

and with x_0 , $\{w_k\}$, $\{v_k\}$, independent and Gaussian vectors (and in addition $\{w_k\}$, $\{v_k\}$ zero mean)

LQG – solution

Let

- $M_k \coloneqq E[\mathbf{w}_k \mathbf{w}_k']$
- $N_k \coloneqq E[\boldsymbol{v}_k \boldsymbol{v}_k']$
- $S := E[(x_0 E[x_0])(x_0 E[x_0])']$

LQG – solution

The optimal controller is $\boldsymbol{u}_k = F_k \widehat{\boldsymbol{x}}_k$, where

- F_k is the LQR gain
- $\widehat{\boldsymbol{x}}_{k+1} = A_k \widehat{\boldsymbol{x}}_k + B_k \boldsymbol{u}_k + \Sigma_{k+1|k+1} C'_{k+1} N_{k+1}^{-1} (\boldsymbol{z}_{k+1} C_{k+1} (A_k \widehat{\boldsymbol{x}}_k + B_k \boldsymbol{u}_k))$
- $\widehat{\mathbf{x}}_0 = E[\mathbf{x}_0] + \Sigma_{0|0} C_0' N_0^{-1} (\mathbf{z}_0 C_0 E[\mathbf{x}_0])$
- and matrices $\Sigma_{k|k}$ are *precomputable* (given in the lecture notes)
- Key property: the estimation portion of the optimal controller is an optimal solution of the problem of estimating the state x_k assuming no control takes place, while the actuator portion is an optimal solution of the control problem assuming perfect state information → separation principle
